			STARS	GAINED
01	sherlock-project/**sherlock** Searches social networks for matching usernames, helping people inspect where a handle appears across online services.	Python	111k	+14.4k
02	ZhuLinsen/**daily_stock_analysis** Combines market data and news into AI-generated stock reports and dashboards for people tracking multiple exchanges.	Python	71.3k	+3.6k
03	ranxianglei/**billion-context** Compresses conversation context for coding agents, aiming to keep long sessions usable within smaller model context windows.	TypeScript	7.2k	+3k
04	homeassistant-ai/**ha-mcp** Connects AI assistants to Home Assistant, helping household administrators configure devices and build automations through conversational tools.	Python	7.7k	+2.2k
05	anthropics/**claude-quickstarts** Provides example Claude applications for developers building customer support, financial analysis and computer control tools using its API.	Python	20.8k	+1.7k
06	google-deepmind/**mujoco** Simulates interacting bodies and joints for researchers working on robotics, biomechanics, animation and other physics-based applications.	C++	17.8k	+1.7k
07	openai/**codex-security** Helps developers find, investigate and fix security vulnerabilities, with repository scans, validation workflows and automated patch generation.	TypeScript	12.8k	+1.5k
08	garrytan/**gbrain** Stores sourced facts for AI assistants, helping users share, correct and retrieve memory across different agents.	TypeScript	32.8k	+1.2k
09	lobehub/**lobehub** Adds AI agents to team chats, letting colleagues delegate work through conversations in tools they already use.	TypeScript	85.3k	+1.2k
10	dsx-ai-factory/**nvke** Manages Kubernetes clusters on NVIDIA GPU infrastructure, helping platform teams operate a service on their own hardware.	Go	1.2k	+1.1k
11	jamiepine/**voicebox** Provides a local voice studio for cloning voices, generating speech and dictating text into other applications.	Python	60.6k	+1.1k
12	every-app/**open-seo** Offers keyword research and rank tracking for website owners, with search optimization workflows accessible to AI agents.	TypeScript	27.6k	+1k
13	rustdesk/**rustdesk** Provides remote desktop access with self-hosting options, helping people control computers while choosing their own server infrastructure.	Rust	129k	+967
14	immich-app/**immich** Manages photos and videos on a self-hosted service, helping people run their own media management system.	TypeScript	119k	+744
15	GyulyVGC/**sniffnet** Monitors network traffic through a cross-platform application, helping people inspect activity on their own computer connections.	Rust	42.7k	+733

```
~ % # A simple search exposes how a reused
username can connect activity across otherwise
separate online services.
~ % gh repo clone sherlock-project/sherlock
```

One username can reveal a scattered footprint

Sherlock searches hundreds of social networks for accounts sharing a name, then saves the results for inspection.

Sherlock starts with a familiar fragment of an online identity: a username. The project says it looks for that name across more than 400 social networks, turning a repetitive series of individual searches into a single operation. It can help someone inspect where a chosen handle appears, including when reviewing their own public footprint.

The basic workflow accepts one username or several. Results are stored in separate text files named after each searched handle. The documented options also include CSV and Excel output, opening results in a browser, and restricting a search to selected sites. Those controls let a user move from a broad sweep to a narrower examination.

The distinction between finding a name and establishing an identity remains essential. A matching handle is a result to investigate, rather than proof that one person controls every account. The README itself warns that ignoring the project's exclusions may produce more false positives, making that option a reason for additional caution.

Installation choices include Python packaging tools and Docker. The maintainers warn that third-party packages for ParrotOS and Ubuntu 24.04 appear broken, and say community packages are not directly supported. Sherlock is MIT-licensed. Its useful idea is the aggregation of public username checks; this account describes the documentation, without claiming an independently tested detection rate.

ha-mcp — Python — +2.2k ★

```
~ % # It brings AI tool use into home
automation, where the choice of account
determines whose authority changes carry.
~ % gh repo clone homeassistant-ai/ha-mcp
```

An AI assistant gets household controls

HA-MCP connects conversational assistants to Home Assistant, making account permissions and connection choices central to the setup.

HA-MCP lets Claude, ChatGPT and other AI assistants configure and automate Home Assistant. The bridge is an MCP server, a connection through which compatible assistants access tools. The project's recommended integration runs inside Home Assistant itself, rather than requiring a separate server installation, and supports its different installation types.

The setup asks an administrator to decide which account the server will act as. One option is a long-lived token from an existing account; the documentation warns that changes then appear under that person's name and that a leaked token works from anywhere. Its safer recommendation is a dedicated administrator account restricted to local access.

Connection choices are equally explicit. Remote and local network access start disabled. Users enable the route their assistant needs, then copy a connection URL. Remote access can use a secret URL or require Home Assistant sign-in. Leaving remote access disabled avoids registering a remote webhook, while local access and the sidebar panel can still work.

The documentation says the in-process integration replaces other installation methods and warns against running multiple copies for one client because connections can hang. File and YAML editing tools are optional and disabled by default. These details make the project more than a conversational convenience: setup determines how much authority an assistant receives. This is a reading of the supplied documentation, rather than a household test.
